Abstract

A field experiment was conducted at Regional Research Station, Paiyur during the year 2017-2018, to improve the physiological and flowering parameters using various plant growth regulators and nutrients. Observations were recorded on physiological and floral parameters. The chlorophyll 'a' (2.21 mg/g), 'b' (1.80 mg/g), total chlorophyll content (2.68 mg/g), chlorophyll index (57.98) and total soluble protein content (13.96 mg/g) were higher in the treatment PBZ (paclobutrazol) @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm) during the main season. The least number of days were taken for initiation of first flowering (61.00 days) in the same treatment during the main season. Number of hermaphrodite flowers per panicle (458.29), length of panicle (43.63 cm) and number of panicles per m² (36.33), were higher during the main season comparing the off season crop in the same treatment.

Introduction

Mango (*Mangifera indica* L.) is an important fruit crop of tropical and sub tropical regions belonging to the family Anacardiaceae with its origin in South East Asia. It exhibits wide variations in growth habit, flowering and fruiting. India is the largest producer of mango occupying about 2.26 lakh thousand hectares, with production of 20.7 million tonnes and productivity about 9.1MT/ha (India Stat 2017-2018). Off season

fruiting in mango refers to bearing of fruits at a time different from the peak season of fruiting. The off season mango production is predominant in tropical countries viz., Thailand, Philippines, Indonesia and some parts of peninsular India especially, Kanyakumari and Courtallam of Tamil Nadu due to favourable temperature and relative humidity prevailing. Orchard efficiency and productivity of mango is affected by problems of biennial bearing, high fruit-drop during

initial stages of fruit development and unfavourable environmental conditions resulting in low fruit set (Murti & Upreti 2000; Kumar et al. 2016). The plant growth retardants especially paclobutrazol, has been found beneficial in combating some of the production related problems. The foliar application of plant growth regulators and nutrients have very important role in improving the flowering and productivity of fruits. Various studies have earlier reported that foliar spray of plant growth regulators and nutrients in different fruit crops cause significant response in improving flowering and yield parameters Hedge et al. (2018). As for physiological, flowering and fruit yield parameters, most of the earlier studies are restricted to the main season and information on off season is scanty. Hence, the present study was taken up to find out the comparison of physiological and flowering attributes of main and off season mango (*Mangifera indica* L.) cv. Bangalora.

Material and Methods

The present investigation was conducted at Regional Research Station, Paiyur during the year 2017-2018. The study was conducted in a farmer's field, which was located at Gurugapatti village, Pochampalli taluk, Krishnagiri district. The experimental site is geographically located at latitude 11°09' N, longitude 76°57' E and altitude 426.76 m above MSL. The experiment was laid out in a Randomized Block Design (RBD), with eight treatments and replicated thrice in both off and main seasons. Twenty five years old uniform sized trees of mango cv. Bangalora spaced at 10 x 10 m were selected for this study. Treatment details of

the experiment are T₁- Absolute control, T₂- PBZ @ 0.75 g a.i. per m² (control), T₃- PBZ @ 0.75 g a.i. per m² + K₂SO₄ (1%), T₄- PBZ @ 0.75 g a.i. per m² + MAP (1%), T₅- PBZ @ 0.75g a.i. per m² + KNO₃ (1%), T₆- PBZ @ 0.75 g a.i. per m² + K₂SO₄ (1%) + NAA (20 ppm), T₇- PBZ @ 0.75g a.i. per m² + MAP (1%) + NAA (20 ppm) and T₈- PBZ @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm). The paclobutrazol concentration was calculated based on the diameter of the tree, and applied @ 0.75 g a.i per m² which was done during the month of June 2017 for off season and September, 2017 for main season. Soil drenching of paclobutrazol was done as per the procedure reported by Burondkar & Gunjate 1992. The foliar sprays of nutrients was imposed at different months viz., August - 15th, September - 15th and October - 15th for off season and November 30th, December - 30th and January - 30th for main season.

Leaf chlorophyll content was determined by Arnon (1949) and expressed in mg/g. Soluble protein content was estimated by Lowery et al. (1951) and expressed in mg/g Chlorophyll index was recorded using portable Chlorophyll Meter (Opti – science model, CCM-200 plus) and the average value was computed using method described by Monje & Bugbee (1992). Randomly selected four shoots per tree were tagged over the tree for collecting the data on days taken for initiation of first flowering after spraying of chemicals. Number of panicles were counted per square meter area at four different locations on a tree with help of wooden frame 1m x 1m dimension and the mean was expressed in numbers. At the time of full bloom, number of hermaphrodite flowers was

counted from the randomly selected four panicles per tree and the mean value was expressed in numbers. Length of panicle was measured at full bloom stage. Four panicles were tagged per tree and the mean value was expressed in centimeter. Statistical analysis of data was done by adopting statistical procedures as per the methods of by Panse & Sukhatme (1985).

Results and Discussion

Impact of plant growth regulators and nutrients on physiological parameters:

The chlorophyll content in plants plays a key role in maintaining the photosynthetic efficiency. The results of the present study revealed that among the two seasons studied, the 'leaf chlorophyll content' and 'chlorophyll index' were higher during the main season than the off season (Table 1). This might be due to the prevailing climatic conditions of the main season where the sunlight interception and temperature were favourable for the development of chlorophyll and photosynthesis. Among the different treatments tried, the highest chlorophyll 'a' content (2.11 mg/g), chlorophyll 'b' content (1.69 mg/g), total chlorophyll content (2.68 mg/g) and chlorophyll index (45.60) was recorded in T₈ - PBZ @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm). Similar observations were reported by many workers

earlier Subbaiah et al. (2018) in mango. The plants treated with paclobutrazol synthesized more cytokinin, which in turn enhanced chloroplast differentiation, chlorophyll biosynthesis and prevented chlorophyll degradation (Xia et al. 2018). Application of paclobutrazol blocks the terpenoid pathway which normally leads to GA (Gibberellic Acid) biosynthesis and an intermediate compound 'phytol' is produced which in turn leads to chlorophyll synthesis (Bai et al. 2004). In the light of above theories, the higher chlorophyll content recorded by application of paclobutrazol. Potassium is responsible for energy production in the form of ATP (Adenosine triphosphate) and NADPH (Nicotinamide Adenine Dinucleotide Phosphate Hydrogen) in chloroplasts by maintaining balanced electric charges in plants (Kumar & Kumar 2007; Yashwanti et al. 2016). Regarding soluble protein, in the present investigation, with regard to two seasons, the highest amount was observed during the main season (Table 1). Regarding the treatments, the maximum 'total soluble protein' was recorded in (13.96 mg/g) plants treated with T₈ - PBZ @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm). In contrast, the lowest soluble protein content was registered in the absolute control where no paclobutrazol was applied.

Impact of plant growth regulators and nutrients on floral parameters:

The timing and intensity of flowering directly determine the yield. Among the two types of flowers noticed, the number of hermaphrodite flowers directly influences the yield. Concerning seasons, the flowering parameters were found to be at a higher level during main season due to the increasing soluble protein enzyme, RuBP carboxylase. This is the most abundant protein present in leaves and involved in CO₂ fixation which directly influences photosynthetic efficiency. Among the different treatments, lesser number of days (61.00 days) were taken for initiation of first flowering in the treatment PBZ @ 0.75 g a.i. m⁻² + KNO₃ (1%) + NAA (20 ppm) (Table 2). It may be due to suppressing activity of paclobutrazol on gibberellins, causing an early reduction of endogenous gibberellic acid levels in shoots by blocking the conversion of *ent kaurene* to *ent kaurenol* (Srilatha et al. 2014). Regarding the other chemical KNO₃ that was applied along with PBZ, it was

already reported that KNO₃ induces nitrate reductase activity, a key enzyme in nitrate assimilatory pathway for amino acid synthesis particularly methionine. Methionine has been reported to promote mango flowering and is a precursor of ethylene (Sudha et al. 2012). The results obtained are in agreement with Subbaiah et al. (2018) and Burondkar et al. (2013) who reported that PBZ application led to 30 days earlier panicle emergence in mango. With respect to the number of hermaphrodite flowers per panicle, compared both the seasons, the highest number of hermaphrodite flowers was recorded in the main season than off season. Regarding the growth regulator and nutrient applications, PBZ @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm) led to the production of highest (458.29) number of hermaphrodite flowers. Paclobutrazol might have resulted in higher reserves of carbohydrates in shoots by its anti - gibberellin nature (Agnihotri et al. 2016; Subbaiah & Reddy 2018).

Table 2. Effect of different plant growth regulators and nutrients on flowering parameters in mango cv. Bangalora

CD (p=0.05)	6.97	9.01	34.84	49.86	1.31	1.79	6.07	1.55

The length of panicle was also found to be greater in the main season than the off season. The favourable environmental factors that prevailed during the main season might have caused this effect. Among these treatments, PBZ @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm) led to the production of highest (43.63 cm) length of panicle. NAA is a known auxin compound which has a profound role on cell division and elongation (Vijayalakshmi & Srinivasan 1998). The ‘number of panicles per m² canopy area’ is one of the major determinants of yield in mango. Among the seasons, the highest number of panicles per m² canopy area was recorded (36.33) in the main season than in the off season. During the main season, the total chlorophyll was greater which caused higher photosynthetic

efficiency thereby the number of panicles could have been increased. Among the different treatments, PBZ @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm) led to the production of higher number of panicles per m² canopy area.

Conclusion

In a nut shell, all the physiological and flowering parameters were found to be at their best level during the main season compared to the off season by application of PBZ @ 0.75 g a.i. per m² + KNO₃ (1%) + NAA (20 ppm). This might be due to the prevailing climatic conditions of the main season.
